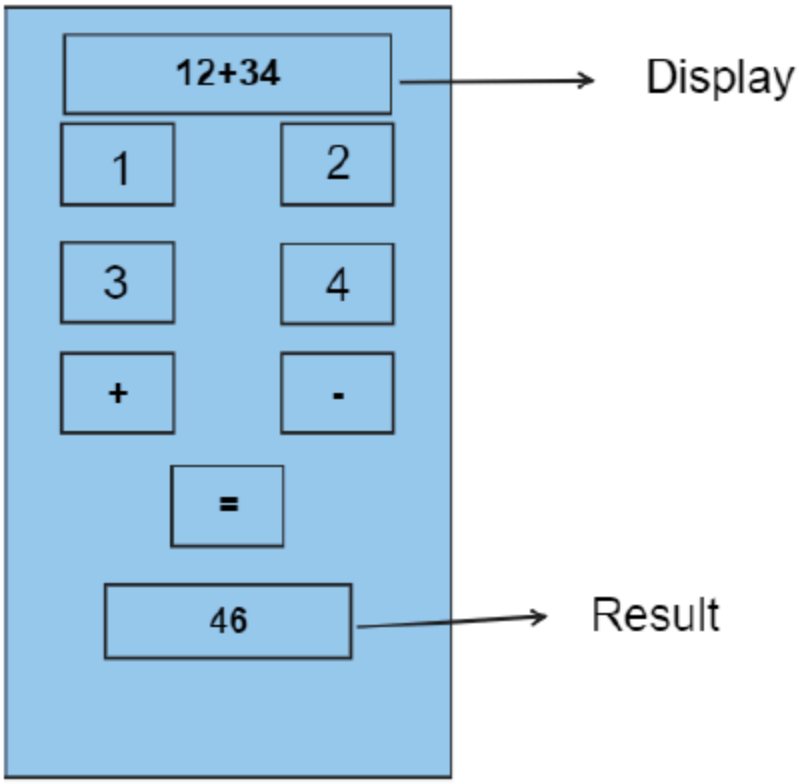
You have build a calculator looks like this:



There will be only one operation(+ or -) at a time.

Here, “Display” and “Result” are the labels and the rest are buttons.

To track which button has been pressed, you should use the parameter (Actionevent e) in the actionPerformed(Actionevent e) method.

To check if button “1” has been pressed, you can write as following inside the method:

```
if(e.getSource() == one){
        //write codes accordingly what should be done if the button “1” is pressed
        // here “one” is the name(reference) of the button object(Button one = new Button(“1”);)
}
```

Hint for solving the whole problem: Try to store the string in the display in a separate string and then use it to evaluate.
